Mathematics of Machine Learning - Summer School

Least Squares. Implicit Bias and Regularization

July 1, 2021

Patrick Rebeschini
Department of Statistics, University of Oxford

Empirical risk minimization: type of regularizations

ERM paradigm:

- ► Consider the *empirical risk* $R(a) = \frac{1}{n} \sum_{i=1}^{n} \phi(f(X_i, a), Y_i)$
- ▶ Compute $A^* \in \operatorname{argmin} R(a)$?

As $n < \infty$, we need to **regularize**. Depending on the problem (i.e. on \mathcal{P}, ℓ, f):

Explicit regularization

Choose class \mathcal{A} Compute $A_{\mathcal{A}}^{\star} \in \arg\min_{a \in \mathcal{A}} R(a)$

Statistics / Computation

Implicit regularization

Choose and tune algorithm aimed at computing $A^\star \in \arg\min_{a \in \mathbb{R}^p} R(a)$

Statistics + Computation

Setup

Assumption: the unknown parameter lies in the span of the data, i.e.

$$w^* = \mathbf{x}^\top \omega = \sum_{i=1}^n \omega_i x_i$$

► Empirical (or sample) second moment matrix:

$$\mathbf{c} := \frac{\mathbf{x}^{\top} \mathbf{x}}{n} = \frac{1}{n} \sum_{i=1}^{n} x_i x_i^{\top} \in \mathbb{R}^{d \times d}$$

c is symmetric positive semi-definite, then

$$\mathbf{c} = \mathbf{u}\boldsymbol{\mu}\mathbf{u}^{\top}$$

$$\mathbf{u}^{\top} = \mathbf{u}^{-1} \text{ and } \boldsymbol{\mu} := \operatorname{diag}(\mu_1, \dots, \mu_r, \underbrace{0, \dots, 0}_{d-r}) \ 0 < \mu_r \leq \dots \leq \mu_1$$

- $ightharpoonup r \leq d$ is the rank of the matrix
- ▶ Pseudoinverse $\mathbf{c}^+ = \mathbf{u} \boldsymbol{\mu}^+ \mathbf{u}^\top$ with $\boldsymbol{\mu}^+ := \operatorname{diag} \left(\frac{1}{\mu_1}, \dots, \frac{1}{\mu_r}, \underbrace{0, \dots, 0}_{1} \right)$

Least Square Regression: with and without Regularization

▶ Unregularized problem $\min\{R(w)\}$:

$$\nabla R(w) = \frac{2}{n} \mathbf{x}^{\top} (\mathbf{x}w - Y) = 0 \qquad \longrightarrow \qquad \mathbf{c}W^{\star} = \frac{\mathbf{x}^{\top} Y}{n}$$

▶ If c is invertible, the unique solution given by

$$W^* = \mathbf{c}^{-1} \frac{\mathbf{x}^\top Y}{n} = w^* + \sigma \mathbf{c}^{-1} \frac{\mathbf{x}^\top \xi}{n}$$

▶ If c is not invertible, infinitely many solutions. Least squares solution:

$$W_{\text{l.s.}}^{\star} = \mathbf{c}^{+} \frac{\mathbf{x}^{\top} Y}{n} = \operatorname{argmin} \left\{ \|w\|_{2} : w \in \operatorname{argmin}_{w \in \mathbb{R}^{d}} R(w) \right\} = \pi w^{\star} + \sigma \mathbf{c}^{+} \frac{\mathbf{x}^{\top} \xi}{n}$$

$$\mathbf{c}^{+} \frac{\mathbf{x}^{\top} \mathbf{x}}{n} = \mathbf{c}^{+} \mathbf{c} = \mathbf{u} \boldsymbol{\mu}^{+} \boldsymbol{\mu} \mathbf{u}^{\top} = \mathbf{u} \operatorname{diag}(1, \dots, 1, \underbrace{0, \dots, 0}_{d-n}) \mathbf{u}^{\top} = \mathbf{u}_{1:r} \mathbf{u}_{1:r}^{\top} = \boldsymbol{\pi}$$

 π is the orthogonal projection operator onto the range of c

► Ridge regression $\min\{R(w) + \lambda \|w\|_2^2\}$: $W_{ridge}^{\star} = (\mathbf{c} + \lambda I)^{-1} \frac{\mathbf{x}^{\top} Y}{n}$

Gradient Descent

Gradient Descent:

$$W_{t+1} = W_t - \frac{\eta}{2} \nabla R(W_t) = (I - \eta \mathbf{c}) W_t + \eta \frac{\mathbf{x}^\top Y}{n}$$

▶ If $W_0 = 0$:

$$W_t = \left(\sum_{k=0}^{t-1} \left(I - \eta \mathbf{c}\right)^k\right) \eta \frac{\mathbf{x}^\top Y}{n} = \underbrace{\operatorname{Inv}_t(\eta \mathbf{c}) \eta \mathbf{c} w}_{\mathbf{E}W_t} + \underbrace{\sigma \operatorname{Inv}_t(\eta \mathbf{c}) \eta \frac{\mathbf{x}^\top \xi}{n}}_{W_t - \mathbf{E}W_t}$$

To run GD no need to compute c, which costs $O(d^2)$

Gradient Descent (Proposition 14.2)

$$W_t = \underbrace{\sum_{i=1}^r (1 - (1 - \eta \mu_i)^t) u_i u_i^\top w^*}_{\mathbf{E}W_t} + \underbrace{\sigma \sum_{i=1}^r \frac{1 - (1 - \eta \mu_i)^t}{\mu_i} u_i u_i^\top \frac{\mathbf{x}^\top \xi}{n}}_{W_t - \mathbf{E}W_t}$$

Proof of Proposition 14.2

- As $\mathbf{u}\mathbf{u}^{\top} = \mathbf{u}^{\top}\mathbf{u} = I$, $\operatorname{Inv}_t(\eta \mathbf{c}) = \sum_{k=0}^{t-1} (\mathbf{u}(I \eta \boldsymbol{\mu})\mathbf{u}^{\top})^k = \mathbf{u}\sum_{k=0}^{t-1} (I \eta \boldsymbol{\mu})^k \mathbf{u}^{\top}$.
- ▶ Using that $\sum_{k=0}^{t-1} x^k = \frac{1-x^t}{1-x}$ for any $x \in \mathbb{R} \setminus \{1\}$ and $\sum_{k=0}^{t-1} 1 = t$, we obtain

$$\begin{split} & \quad \text{Using that } \sum_{k=0}^{t-1} x^k = \frac{1-x^t}{1-x} \text{ for any } x \in \mathbb{R} \setminus \{1\} \text{ and } \sum_{k=0}^{t-1} 1 = t \text{, we obtain} \\ & \quad \text{Inv}_t(\eta \mathbf{c}) = \mathbf{u} \operatorname{diag} \left(\frac{1-(1-\eta \mu_1)^t}{\eta \mu_1}, \ldots, \frac{1-(1-\eta \mu_r)^t}{\eta \mu_r}, t, \ldots, t \right) \mathbf{u}^\top \\ & = \mathbf{u} \operatorname{diag} \left(\frac{1-(1-\eta \mu_1)^t}{\eta \mu_1}, \ldots, \frac{1-(1-\eta \mu_r)^t}{\eta \mu_r}, 0, \ldots, 0 \right) \mathbf{u}^\top + \mathbf{u} \operatorname{diag}(0, \ldots, 0, t, \ldots, t) \mathbf{u}^\top \\ & = \mathbf{u}_{1:r} \operatorname{diag} \left(\frac{1-(1-\eta \mu_1)^t}{\eta \mu_1}, \ldots, \frac{1-(1-\eta \mu_r)^t}{\eta \mu_r} \right) \mathbf{u}_{1:r}^\top + t \mathbf{u}_{r+1:d} \mathbf{u}_{r+1:d}^\top \\ & = \mathbf{u}_{1:r} \operatorname{diag} \left(1-(1-\eta \mu_1)^t, \ldots, 1-(1-\eta \mu_r)^t \right) \mathbf{u}_{1:r}^\top \mathbf{u}_{1:r} \operatorname{diag} \left(\frac{1}{\eta \mu_1}, \ldots, \frac{1}{\eta \mu_r} \right) \mathbf{u}_{1:r}^\top + t (I-\pi) \\ & = \mathbf{u}(I-(I-\eta \mu)^t) \mathbf{u}^\top (\eta \mathbf{c})^+ + t (I-\pi) \\ & = (I-\mathbf{u} \mathbf{s}^t \mathbf{u}^\top) (\eta \mathbf{c})^+ + t (I-\pi). \end{split}$$

- ightharpoonup By the properties of the pseudoinverse, we have $(I \pi)\mathbf{x}^{\top} = 0$. If fact, for a
- generic matrix \mathbf{m} it can be shown that $(\mathbf{m}^{\top}\mathbf{m})^{+}\mathbf{m}^{\top} = \mathbf{m}^{+}, \mathbf{m}^{+}\mathbf{m}\mathbf{m}^{\top} = \mathbf{m}^{\top}$. As $\pi = c^+c$ by (14.2) and $c = \mathbf{x}^\top \mathbf{x}/n$ by definition, by two properties above: $(I-\pi)\mathbf{x}^{\top} = (I-(\mathbf{x}^{\top}\mathbf{x})^{+}\mathbf{x}^{\top}\mathbf{x})\mathbf{x}^{\top} = (I-\mathbf{x}^{+}\mathbf{x})\mathbf{x}^{\top} = \mathbf{x}^{\top}-\mathbf{x}^{+}\mathbf{x}\mathbf{x}^{\top} = \mathbf{x}^{\top}-\mathbf{x}^{\top} = 0.$

$$(I-\pi)\mathbf{x}^{\top} = (I-(\mathbf{x}^{\top}\mathbf{x})^{+}\mathbf{x}^{\top}\mathbf{x})\mathbf{x}^{\top} = (I-\mathbf{x}^{+}\mathbf{x})\mathbf{x}^{\top} = \mathbf{x}^{\top}-\mathbf{x}^{+}\mathbf{x}\mathbf{x}^{\top} = \mathbf{x}^{\top}-\mathbf{x}^{\top} = 0.$$

► So, using that $\mathbf{c} = \mathbf{u} \boldsymbol{\mu} \mathbf{u}^{\top}$ we find $\operatorname{Inv}_t(\eta \mathbf{c}) \eta \mathbf{c} = (I - \mathbf{u} \mathbf{s}^t \mathbf{u}^{\top})$, and

$$W_t - \mathbf{E}W_t = \sigma \operatorname{Inv}_t(\eta \mathbf{c}) \eta \frac{\mathbf{x}^\top \xi}{n} = \sigma (I - \mathbf{u}\mathbf{s}^t \mathbf{u}^\top) \mathbf{c}^+ \frac{\mathbf{x}^\top \xi}{n}.$$

Implicit Bias

Implicit Bias (Proposition 14.3)

$$\lim_{t \to \infty} W_t = \underbrace{\boldsymbol{\pi} \boldsymbol{w}^{\star}}_{\lim_{t \to \infty} \mathbf{E} W_t} + \underbrace{\boldsymbol{\sigma} \mathbf{c}^{+} \mathbf{x}^{\top} \boldsymbol{\xi}}_{\lim_{t \to \infty} (W_t - \mathbf{E} W_t)} = W_{\mathsf{l.s.}}^{\star}$$

with rate given by

$$\|W_t - W_{\text{l.s.}}^{\star}\|_2 \le (1 - \eta \mu_r)^t \|w^{\star}\|_2 + \frac{\sigma}{\sqrt{n}} \frac{(1 - \eta \mu_1)^t}{\mu_r} \left\| \frac{\mathbf{x}^{\top} \xi}{\sqrt{n}} \right\|_2$$

Where does implicit bias come from?

$$x_{s+1} = \underset{y \in \mathbb{R}^d}{\operatorname{argmin}} \left\{ f(x_s) + \nabla f(x_s)^{\top} (y - x_s) + \frac{1}{2\eta_s} ||y - x_s||_2^2 \right\}$$

Implicit Regularization

Implicit Regularization (Theorem 14.5)

$$\|W_t - w^\star\|_2 \leq \underbrace{\|\mathbf{E}W_t - \boldsymbol{\pi}w^\star\|_2}_{\text{bias error}} + \underbrace{\|W_t - \mathbf{E}W_t\|_2}_{\text{concentration error}} + \underbrace{\|w^\star - \boldsymbol{\pi}w^\star\|_2}_{\text{approximation error}}$$

Let $\eta^* \leq \frac{1}{\mu_1}$, $t^* \geq \frac{1}{\log(1/(1-\eta\mu_r))} \log\left(\frac{\|w^*\|_2}{\sigma} \frac{\sqrt{n}}{\bar{c}}\right)$ for a given $c \in (0,1)$. Then,

$$\boxed{\mathbf{P}\bigg(\|W_{t^*} - w^*\|_2 \le 2\sigma \frac{\tilde{c}}{\sqrt{n}} + \|w^* - \pi w^*\|_2\bigg) \ge 1 - \delta}$$

with
$$\tilde{c} = \frac{1}{\mu_r} \sqrt{\sum_{i=1}^r \mu_i + c \sum_{i=1}^r \frac{\mu_i^2}{\mu_1}}$$
 and $\delta = e^{-\frac{c^2}{8} \sum_{i=1}^r (\mu_i/\mu_1)^2}$

GD solves the problem optimally (stats and computation) if:

- lacktriangle Eigenvalues $\{\mu_1,\ldots,\mu_r\}$ are upper and lower bounded by univ. constants
- Signal-to-noise ratio $\frac{\|w^*\|_2}{\sigma}$ is upper bounded by a universal constant

Proof of Theorem 14.5 (Part I)

▶ Bias term: from Proposition 14.2, using that $\pi = \sum_{i=1}^{r} u_i u_i^{\mathsf{T}}$, we have

$$\|\mathbf{E}W_{t} - \boldsymbol{\pi}w^{\star}\|_{2} = \left\| \sum_{i=1}^{r} (1 - (1 - \eta\mu_{i})^{t}) u_{i} u_{i}^{\top} w^{\star} - \sum_{i=1}^{r} u_{i} u_{i}^{\top} w^{\star} \right\|_{2}$$

$$= \left\| - \sum_{i=1}^{r} (1 - \eta\mu_{i})^{t} u_{i} u_{i}^{\top} w^{\star} \right\|_{2}$$

$$\leq \left\| - \sum_{i=1}^{r} (1 - \eta\mu_{i})^{t} u_{i} u_{i}^{\top} \right\| \|w^{\star}\|_{2} \leq (1 - \eta\mu_{r})^{t} \|w^{\star}\|_{2}$$

Concentration term:

$$\|W_t - \mathbf{E}W_t\|_2 = \left\|\sigma \sum_{i=1}^r \frac{1 - (1 - \eta \mu_i)^t}{\mu_i} u_i u_i^\top \frac{\mathbf{x}^\top \boldsymbol{\xi}}{n}\right\|_2$$

$$\leq \sigma \left\|\sum_{i=1}^r \frac{1 - (1 - \eta \mu_i)^t}{\mu_i} u_i u_i^\top \right\| \frac{\|\mathbf{x}^\top \boldsymbol{\xi}\|_2}{n}$$

$$\leq \frac{\sigma}{\sqrt{n}} \frac{1 - (1 - \eta \mu_1)^t}{\mu_r} \frac{\|\mathbf{x}^\top \boldsymbol{\xi}\|_2}{\sqrt{n}}.$$

Proof of Theorem 14.5 (Part II)

- ▶ The random vector $V:=\frac{\mathbf{x}^{\top}\boldsymbol{\xi}}{\sqrt{n}}$ is Gaussian with mean 0 and second moment matrix \mathbf{c}
- We will now show that $\|V\|_2^2 = (\frac{\|\mathbf{x}^T\xi\|_2}{\sqrt{n}})^2$ has the same distribution as $\sum_{i=1}^r \mu_i Z_i^2$, where Z_1, \ldots, Z_r are i.i.d. standard Gaussian random variables.
- ▶ Let $\mathbf{c}^{1/2} = \mathbf{u} \boldsymbol{\mu}^{1/2} \mathbf{u}^{\top}$ be the square root of the matrix \mathbf{c} , with $\boldsymbol{\mu}^{1/2} = \operatorname{diag}(\sqrt{\mu_1}, \dots, \sqrt{\mu_r}, 0, \dots, 0)$. Let $Z = (Z_1, \dots, Z_d) \in \mathbb{R}^d$ be a Gaussian random vector with mean 0 and covariance I. Then, the random vector V has the same distribution as the random vector $T = \mathbf{c}^{1/2} \mathbf{u} Z$. In fact, T is Gaussian being a linear combination of a Gaussian vector and its variance is given by

$$\mathbf{E}TT^{\top} = \mathbf{E}[\mathbf{c}^{1/2}\mathbf{u}ZZ^{\top}\mathbf{u}^{\top}\mathbf{c}^{1/2}] = \mathbf{c}^{1/2}\mathbf{u}\mathbf{E}[ZZ^{\top}]\mathbf{u}^{\top}\mathbf{c}^{1/2} = \mathbf{c}^{1/2}\mathbf{u}\mathbf{u}^{\top}\mathbf{c}^{1/2} = \mathbf{c}.$$

ightharpoonup Then, as $\mathbf{c} = \mathbf{u} \boldsymbol{\mu} \mathbf{u}^{\mathsf{T}}$, we find

$$\left(\frac{\|\mathbf{x}^{\top}\boldsymbol{\xi}\|_{2}}{\sqrt{n}}\right)^{2} = \|V\|_{2}^{2} = V^{\top}V \sim T^{\top}T = Z^{\top}\mathbf{u}^{\top}\mathbf{c}\mathbf{u}Z$$
$$= Z^{\top}\mathbf{u}^{\top}\mathbf{u}\boldsymbol{\mu}\mathbf{u}^{\top}\mathbf{u}Z = Z^{\top}\boldsymbol{\mu}Z = \sum_{i=1}^{r} \mu_{i}Z_{i}^{2}$$

Proof of Theorem 14.5 (Part III)

- ▶ In particular, $\mathbf{E}\left[\left(\frac{\|\mathbf{x}^{\top}\mathbf{\xi}\|_2}{\sqrt{n}}\right)^2\right] = \mathbf{E}[\|V\|_2^2] = \sum_{i=1}^r \mu_i \mathbf{E}[Z_i^2] = \sum_{i=1}^r \mu_i$.
- From Problem 3.3 in the Problem Sheets, recall that each Z_i^2 is sub-exponential with parameters $\nu^2=4$ and c=4, namely:

$$\mathbf{E}e^{t(Z_i^2-1)} \le e^{\nu^2 t^2/2}$$
 for any $t \in (-1/c, 1/c)$.

▶ By Chernoff's bound we have, for any $\varepsilon, t > 0$,

$$\begin{split} \mathbf{P}(\|V\|_{2}^{2} - \mathbf{E}[\|V\|_{2}^{2}] &\geq \varepsilon) \leq e^{-t\varepsilon} \mathbf{E} e^{t(\|V\|_{2}^{2} - \mathbf{E}[\|V\|_{2}^{2})} = e^{-t\varepsilon} \mathbf{E} e^{t\sum_{i=1}^{r} \mu_{i}(Z_{i}^{2} - 1)} \\ &= e^{-t\varepsilon} \prod_{i=1}^{r} \mathbf{E} e^{t\mu_{i}(Z_{i}^{2} - 1)}. \end{split}$$

If $t\mu_1 < 1/4$, then the previous result yields

$$\mathbf{P}(\|V\|_2^2 - \mathbf{E}[\|V\|_2^2] \ge \varepsilon) \le e^{-t\varepsilon} \prod_{i=1}^r e^{2t^2\mu_i^2} = e^{-t\varepsilon + 2t^2 \sum_{i=1}^r \mu_i^2}.$$

The smallest upper bound is obtained by choosing $t=\frac{\varepsilon}{4\sum_{i=1}^{r}\mu_{i}^{2}}$ and yields

$$\mathbf{P}\left(\frac{\|\mathbf{x}^{\top}\boldsymbol{\xi}\|_{2}}{\sqrt{n}} \geq \sqrt{\sum_{i=1}^{r} \mu_{i} + \varepsilon}\right) = \mathbf{P}\left(\left(\frac{\|\mathbf{x}^{\top}\boldsymbol{\xi}\|_{2}}{\sqrt{n}}\right)^{2} - \sum_{i=1}^{r} \mu_{i} \geq \varepsilon\right) \leq e^{-\varepsilon^{2}/(8\sum_{i=1}^{r} \mu_{i}^{2})}.$$

Proof of Theorem 14.5 (Part IV)

▶ Choosing $\varepsilon = c \sum_{i=1}^r \mu_i^2/\mu_1$, where c is any positive constant strictly less than 1,

$$\mathbf{P}\left(\frac{\|\mathbf{x}^{\top}\xi\|_{2}}{\sqrt{n}} < \sqrt{\sum_{i=1}^{r} \mu_{i} + c \sum_{i=1}^{r} \frac{\mu_{i}^{2}}{\mu_{1}}}\right) \ge 1 - e^{-\frac{c^{2}}{8} \sum_{i=1}^{r} (\mu_{i}/\mu_{1})^{2}}.$$

▶ Hence, so far we proved that for any $c \in (0,1)$ we have

$$\mathbf{P}\bigg(\|W_t - w^\star\|_2 \le (1 - \eta \mu_r)^t \|w^\star\|_2 + \frac{\sigma}{\sqrt{n}} \tilde{c} + \|w^\star - \pi w^\star\|_2\bigg) \ge 1 - \delta,$$
 with $\tilde{c} = \frac{1}{\mu_r} \sqrt{\sum_{i=1}^r \mu_i + c \sum_{i=1}^r \frac{\mu_i^2}{\mu_i}}$ and $\delta = e^{-\frac{c^2}{8} \sum_{i=1}^r (\mu_i/\mu_1)^2}$.

► Choosing t^* such that $(1 - \eta \mu_r)^{t^*} \|w^*\|_2 = \frac{\sigma}{\sqrt{n}} \tilde{c}$ yields the final result.
